Infrared spectroscopy (IR spectroscopy or vibrational spectroscopy) involves the interaction of infrared radiation with matter. It covers a range of techniques, mostly based on absorption spectroscopy. As with all spectroscopic techniques, it can be used to identify and study chemicals. Samples may be solid, liquid, or gas.

Molecular Spectroscopy. Infrared and Raman spectroscopy provide information about the vibrational and vibrational-rotational modes of molecules. The latter are generally observed in the gas phase, where the molecules are able to rotate freely. In condensed phases, however, only vibrational modes are observed. Infrared and Raman spectroscopy are complementary techniques, as symmetry dictates that transitions allowed in one may be forbidden in the other.

Infrared spectroscopy is the study of how molecules absorb infrared radiation and ultimately convert it to heat. By examining how this occurs, we will not only learn about how infrared radiation is absorbed, but we will also learn about molecular structure and how the study of
